3.4	Comparing output . . . . .	8
<b>4</b>	<b>Clean up actions</b>	<b>11</b>

## 1 This vignette

We provide here example calls of all segmentation methods, with different options for methods, as well as different options for type of input object and clustering. This is provided here as both extended help and as a simple way of checking that all the functions can be run and yield the same results regardless of type of input and clustering.

## 2 Creating objects

We must ensure that we can run this vignette as stand alone. Thus, we load the package and create all necessary objects. This repeats work done in the main vignette.

We first try to move to the “/tmp” directory, if it exists. If it does not, the code will be executed in your current directory.

```
> try(setwd("~/tmp"))  
  
> library(ADaCGH2)  
> ## loading in-RAM objects  
> data(inputEx)  
> summary(inputEx)
```

### 3 The examples

#### 3.1 RAM objects and forking

```

> cbs.RAM.fork <- pSegmentDNACopy(cgh.dat, chrom.dat)
> cbs.mad.RAM.fork <- pSegmentDNACopy(cgh.dat, chrom.dat,merging = "MAD")
> cbs.none.RAM.fork <- pSegmentDNACopy(cgh.dat, chrom.dat, merging = "none")
> hmm.RAM.fork <- pSegmentHMM(cgh.dat, chrom.dat, merging = "mergeLevels")
> hmm.mad.RAM.fork <- pSegmentHMM(cgh.dat, chrom.dat, merging = "MAD")
> hs.ml.RAM.fork <- pSegmentHaarSeg(cgh.dat, chrom.dat,
+                               merging = "mergeLevels")
> hs.mad.RAM.fork <- pSegmentHaarSeg(cgh.dat, chrom.dat,
+                               merging = "MAD")
> glad.RAM.fork <- pSegmentGLAD(cgh.dat, chrom.dat)
> biohmm.RAM.fork <- pSegmentBioHMM(cgh.dat,
+                                chrom.dat,
+                                pos.dat,
+                                merging = "mergeLevels")
> biohmm.mad.RAM.fork <- pSegmentBioHMM(cgh.dat,

```

```

+             chrom.dat,
+             pos.dat,
+             merging = "MAD")
> biohmm.mad.bic.RAM.fork <- pSegmentBioHMM(cgh.dat,
+             chrom.dat,
+             pos.dat,
+             merging = "MAD",
+             aic.or.bic = "BIC")
> cghseg.merge.RAM.fork <- pSegmentCGHseg(cgh.dat,
+             chrom.dat,
+             merging = "mergeLevels")
> cghseg.mad.RAM.fork <- pSegmentCGHseg(cgh.dat,
+             chrom.dat,
+             merging = "MAD")
> cghseg.none.RAM.fork <- pSegmentCGHseg(cgh.dat,
+             chrom.dat,
+             merging = "none")
> waves.merge.RAM.fork <- pSegmentWavelets(cgh.dat,
+             chrom.dat, merging = "mergeLevels")
> waves.mad.RAM.fork <- pSegmentWavelets(cgh.dat,
+             chrom.dat, merging = "MAD")
> waves.none.RAM.fork <- pSegmentWavelets(cgh.dat,
+             chrom.dat, merging = "none")
>

```

### 3.2 *ff* objects and cluster

Compared to the section 3.1, the main differences are that we explicitly set the `typeParall` argument to "cluster" (the default is "fork") and the change in the names of the input data (which now refer to the names of the RData objects that contain the *ff* objects).

```

> cbs.ff.cluster <- pSegmentDNACopy("cghData.RData", "chromData.RData",
+             typeParall = "cluster")
> cbs.mad.ff.cluster <- pSegmentDNACopy("cghData.RData", "chromData.RData",
+             merging = "MAD",
+             typeParall = "cluster")
> cbs.none.ff.cluster <- pSegmentDNACopy("cghData.RData", "chromData.RData",
+             merging = "none",
+             typeParall = "cluster")
> hmm.ff.cluster <- pSegmentHMM("cghData.RData", "chromData.RData",
+             merging = "mergeLevels",
+             typeParall = "cluster")
> hmm.mad.ff.cluster <- pSegmentHMM("cghData.RData", "chromData.RData",
+             merging = "MAD",
+             typeParall = "cluster")
> hs.ml.ff.cluster <- pSegmentHaarSeg("cghData.RData", "chromData.RData",
+             merging = "mergeLevels",
+             typeParall = "cluster")
> hs.mad.ff.cluster <- pSegmentHaarSeg("cghData.RData", "chromData.RData",
+             merging = "MAD", typeParall = "cluster")
> glad.ff.cluster <- pSegmentGLAD("cghData.RData", "chromData.RData",
+             typeParall = "cluster")
+

```

```

> biohmm.ff.cluster <- pSegmentBioHMM("cghData.RData",
+                                     "chromData.RData",
+                                     "posData.RData",
+                                     merging = "mergeLevels",
+                                     typeParall = "cluster")
> biohmm.mad.ff.cluster <- pSegmentBioHMM("cghData.RData",
+                                          "chromData.RData",
+                                          "posData.RData",
+                                          merging = "MAD",
+                                          typeParall = "cluster")
> biohmm.mad.bic.ff.cluster <- pSegmentBioHMM("cghData.RData",
+                                              "chromData.RData",
+                                              "posData.RData",
+                                              merging = "MAD",
+                                              aic.or.bic = "BIC",
+                                              typeParall = "cluster")
> cghseg.merge.ff.cluster <- pSegmentCGHseg("cghData.RData",
+                                           "chromData.RData",
+                                           merging = "mergeLevels",
+                                           typeParall = "cluster")

>

```

### 3.3 *ff* objects and forking

The main difference with section 3.2 is the argument `typeParall`; we did not need to pass it explicitly (since the default is `fork`), but we will do for clarity.

```

> cbs.ff.fork <- pSegmentDNACopy("cghData.RData", "chromData.RData",
+                               typeParall = "fork")
> cbs.mad.ff.fork <- pSegmentDNACopy("cghData.RData", "chromData.RData",
+                                    merging = "MAD",
+                                    typeParall = "fork")

```

```

> cbs.none.ff.fork <- pSegmentDNACopy("cghData.RData", "chromData.RData",
+                                     merging = "none", typeParall = "fork")
> hmm.ff.fork <- pSegmentHMM("cghData.RData", "chromData.RData",
+                             merging = "mergeLevels", typeParall = "fork")
> hmm.mad.ff.fork <- pSegmentHMM("cghData.RData", "chromData.RData",
+                                 merging = "MAD", typeParall = "fork")
> hs.ml.ff.fork <- pSegmentHaarSeg("cghData.RData", "chromData.RData",
+                                  merging = "mergeLevels", typeParall = "fork")
> hs.mad.ff.fork <- pSegmentHaarSeg("cghData.RData", "chromData.RData",
+                                  merging = "MAD", typeParall = "fork")
> glad.ff.fork <- pSegmentGLAD("cghData.RData", "chromData.RData",
+                               typeParall = "fork")
> biohmm.ff.fork <- pSegmentBioHMM("cghData.RData",
+                                  "chromData.RData",
+                                  "posData.RData",
+                                  merging = "mergeLevels",
+                                  typeParall = "fork")
> biohmm.mad.ff.fork <- pSegmentBioHMM("cghData.RData",
+                                       "chromData.RData",
+                                       "posData.RData",
+                                       merging = "MAD",
+                                       typeParall = "fork")
> biohmm.mad.bic.ff.fork <- pSegmentBioHMM("cghData.RData",
+                                           "chromData.RData",

### 3.4 Comparing output

Here we verify that using different input and clustering methods does not change the results. Before carrying out the comparisons, however, we open the *ff* objects gently.

First, we will open the objects created above (same objects as were also created in the main vignette, in section "Carrying out segmentation and calling"). Instead of inserting many calls to each individual object, we open all available objects that match `ff.cluster`. To do that quickly we store the names of the objects

```
> ff.cluster.obj <- ls(pattern = "*.ff.cluster")
```

pages with the string "TRUE")

```
> tmpout <-  
+   capture.output(  
+     lapply(ff.cluster.obj, function(x) lapply(get(x), open))  
+   )
```

We repeat that operation with the output from section 3.3:

```
> ff.fork.obj <- ls(pattern = "*.ff.fork")  
> tmpout <-  
+   capture.output(  
+     lapply(ff.fork.obj, function(x) lapply(get(x), open))  
+   )  
>
```

And we create the list of results from the RAM and forking runs (no need for special opening here, since these are not *ff* objects)

```
> RAM.fork.obj <- ls(pattern = "*.RAM.fork")
```

We can now compare the output. We want to compare the output from three different methods, so we need to run three comparisons (this is what we did explicitly in the help for `pSegment`). Since this is a very repetitive operation, we define a small utility function that will return TRUE if both components (`outSmoothed` and `outState`) of all three objects are identical. (Since the function will take as input not an actual object, but a name, we use `get` inside the function.)

We use `all.equal` to compare the output from the smoothing, to allow for possible numerical fuzz (that could result from differences in storage). When comparing the assigned state, however, we check for exact identity.

```
> identical3 <- function(x, y, z) {  
+   comp1 <- all.equal(get(x)$outSmoothed[ , ], get(y)$outSmoothed[ , ])  
+   comp2 <- all.equal(get(y)$outSmoothed[ , ], get(z)$outSmoothed[ , ])  
+   comp3 <- identical(get(x)$outState[ , ], get(y)$outState[ , ])  
+   comp4 <- identical(get(y)$outState[ , ], get(z)$outState[ , ])  
+   if (!all(isTRUE(comp1), isTRUE(comp2), comp3, comp4)) {  
+     cat(paste("Comparing ", x, y, z, "\n",  
+       "not equal: some info from comparisons.\n",  
+       "\n comp1 = ", paste(comp1, sep = " ", collapse = "\n  "),  
+       "\n comp2 = ", paste(comp2, sep = " ", collapse = "\n  "),  
+       "\n comp3 = ", paste(comp3, sep = " ", collapse = "\n  "),  
+       "\n comp4 = ", paste(comp4, sep = " ", collapse = "\n  "),
```

```
+         "\n\n"))
+     return(FALSE)
+ } else {
+     TRUE
+ }
+ }
```

You should expect most (though not necessarily all) the comparisons to yield a TRUE. In some cases, however, different runs of the same method might not yield the same results (e.g., CBS, HMM, etc). If you get non-identical results, you can try running those methods a few times, to check for differences.

```
> mapply(identical3, RAM.fork.obj,
+         ff.fork.obj, ff.cluster.obj)
```

(Of course, we depend on the lists of names of objects having the output from the same method and option in the same position, which is the case in these examples).

## 4 Clean up actions

These are not strictly necessary, but we will explicitly stop the cluster. In this vignette, we will not execute the code below to remove the directory we created or the objects, in case you want to check them out or play around with them, but the code is below.

To make sure there are no file permission problems, we add code below to explicitly delete some of the "ff" files and objects (and we wait a few seconds to allow pending I/O operations to happen before we delete the directory).

```

> parallel::stopCluster(cl2)

> ## This is the code to remove all the files we created
> ## and the temporary directory.
> ## We are not executing it!
>
> load("chromData.RData")
> load("posData.RData")
> load("cghData.RData")
> delete(cghData); rm(cghData)
> delete(posData); rm(posData)
> delete(chromData); rm(chromData)
> tmpout <-
+   capture.output(
+     lapply(ff.fork.obj, function(x) {
+       lapply(get(x), delete)}))
> rm(list = ff.fork.obj)
> tmpout <-

```

```
+   capture.output(  
+     lapply(ff.cluster.obj, function(x) {  
+       lapply(get(x), delete)}))  
> rm(list = ff.cluster.obj)  
> setwd(originalDir)  
> print(getwd())  
> Sys.sleep(3)  
> unlink("ADaCGH2_vignette_tmp_dir", recursive = TRUE)  
> Sys.sleep(3)
```
